February 2, 2018

Administrative stuff

- Scores for PS1 are out.
- PS2 is currently being graded, should be done by next Thursday.
- PS3 is available now.
- I finally added recitation slides to my github page:
 - https://github.com/seblaud/3104-Recitations

Basics of recurrence relations

- What are they?
- Why do we need them?
- How do we "solve" them?

Recurrence relations, cont.

- Recurrence relations specify the n-th value in a sequence based on previous value(s) in the sequence (hence the term recurrence / recursion)
 - Note that recurrence relations can be based on multiple previous values, e.g. T(n) = T(n-1) + T(n-2)
- Recurrence relations arise naturally when analyzing the complexity of recursive algorithms (like merge sort)

Expansion method

- One way to solve recurrence relations is via the so-called "expansion method"
- This method basically involves expanding the recurrence until a pattern is discernible, then applying the base case and solving

Recurrence relation examples

Consider the recurrence relation

$$T(n) = T(n-1) + 3n$$
$$T(0) = 1$$

- Find the pattern by using the expansion method
- Apply the base case
- ullet Then solve to get a ${\mathcal O}$ bound

$$T(n) = T(n-1) + 3n$$

= $T(n-2) + 3(n-1) + 3n$
= $T(n-3) + 3(n-2) + 3(n-1) + 3n$

• What's the pattern?

$$T(n) = T(n-k) + 3(n-k+1) + \ldots + 3n$$

- Base case?
- The base case is T(0), which will occur when n k = 0

$$T(n) = T(0) + 3(1) + 3(2) + \dots + 3n$$

$$= T(0) + 3(1 + 2 + 3 + \dots + n)$$

$$= T(0) + 3\left(\frac{n(n+1)}{2}\right)$$

$$= 1 + \frac{3}{2}n^2 + \frac{3}{2}n$$

$$\in \mathcal{O}(n^2)$$

Another example

Consider the recurrence relation

$$T(n) = T\left(\frac{n}{2}\right) + 1$$
 $T(1) = 1$

- Here, n > 1 and is a power of 2.
- Solve it and prove it by induction.

Solution

$$T(n) = T\left(\frac{n}{2}\right) + 1$$

$$= T\left(\frac{n}{4}\right) + 2$$

$$= T\left(\frac{n}{8}\right) + 3$$

$$\vdots$$

$$= T\left(\frac{n}{2^k}\right) + k$$

Base case

- Eventually we should end up at our base case.
- Via our pattern, this would mean that $\frac{n}{2^k} = 1 \Rightarrow k = \log n$.

Plug it in

• Plugging this value in for k, we get:

$$T(n) = T(1) + \log n$$
$$= \log n + 1$$

- This is the solution to the recurrence relation.
- But really, we should prove that it is in fact correct.
- → Induction!

Proof of correctness

- So we want to show that the solution to our recurrence relation is $T(n) = \log n + 1$.
- Base case?
 - $T(1) = \log 1 + 1 = 1$

Induction hypothesis & step

• Assume that $T(k) = \log k + 1$.

$$T(2k) = T\left(\frac{2k}{2}\right) + 1$$

$$= T(k) + 1$$

$$= \log k + 2$$

$$= \log k + \log 2 + 1$$

$$= \log(2k) + 1$$

• So we're done.

Recurrence Tree method

- Visualization of the recurrence relation.
- Draw a recursion tree and keep track of the cost at each recursive level.
- Sum up the cost of all recursion levels.
- Remember the general form of a recurrence relation:
 - $T(n) = aT(\frac{n}{b}) + f(n)$.
 - Here, a represents the number of subproblems to split into.
 - b represents the fractional size of each subproblem.
 - f(n) represents the cost of the subproblem of size n.

Example

- Consider the recurrence relation $T(n) = 3T(\frac{n}{4}) + cn^2$.
- Let's start by translating this into a recursion tree.
- At each level of recursion, split into 3 subproblems of size $\frac{n}{4}$.
- How many levels are there?
 - Bottom level has subproblems of size 1, and subproblems at level *i* have size $\frac{n}{4i}$.
 - Thus, we need $\frac{n}{4^i} = 1 \Rightarrow i = \log_4 n$.
 - This means our tree depth is $\log_4 n$.

- Since each problem splits into 3 subproblems and our tree depth is $\log_4 n$, the bottom level has $3^{\log_4 n}$ nodes.
- $3^{\log_4 n} = n^{\log_4 3}$, and each node has a constant cost, this means that the cost of the bottom level is $\Theta(n^{\log_4 3})$.

So the total cost of this recursion tree is given by

$$T(n) = cn^{2} + \left(\frac{3}{16}\right)cn^{2} + \left(\frac{3}{16}\right)^{2}cn^{2} + \dots + \left(\frac{3}{16}\right)^{\log_{4} n - 1}cn^{2}$$

$$+ \Theta(n^{\log_{4} 3})$$

$$= \sum_{i=0}^{\log_{4} n - 1} \left(\frac{3}{16}\right)^{i}cn^{2} + \Theta(n^{\log_{4} 3})$$

$$< \sum_{i=0}^{\infty} \left(\frac{3}{16}\right)^{i}cn^{2} + \Theta(n^{\log_{4} 3})$$

$$= \frac{1}{1 - \frac{3}{16}}cn^{2} + \Theta(n^{\log_{4} 3})$$

$$= \frac{16}{13}cn^{2} + \Theta(n^{\log_{4} 3})$$

$$= \mathcal{O}(n^{2})$$

Master method

- Generalization of solutions to recurrences.
- Learn the Master Theorem.
- Easy to use, but care must be taken to use the Master method properly.

Master Theorem

Master Theorem

For a recurrence relation of the form

$$T(n) = aT\left(\frac{n}{b}\right) + f(n)$$

where $a \ge 1$, b > 1, c > 0.

$$T(n) = \begin{cases} \Theta(n^{\log_b a}) & \text{if} \quad f(n) = \mathcal{O}(n^{\log_b a - \epsilon}) \\ \Theta(n^{\log_b a} \log n) & \text{if} \quad f(n) = \Theta(n^{\log_b a}) \\ \Theta(f(n)) & \text{if} \quad f(n) = \Omega(n^{\log_b a + \epsilon}) \end{cases}$$

Note that the third case also requires that $af(\frac{n}{b}) \le cf(n)$ for some constant c < 1 and for all sufficiently large n. Also, $\epsilon > 0$ for case 1 and case 3.

Example

• Consider the following recurrence relation:

$$T(n) = 4T\left(\frac{n}{2}\right) + n$$

- What are the coefficients a, b in our general recurrence form?
- How about f(n)?
- Does the Master method apply to this recurrence? Which case?

- a = 4, b = 2.
- Note that $f(n) = n = \mathcal{O}(n^{\log_2 4 \epsilon}) = \mathcal{O}(n^{2 \epsilon})$, which is true for some $0 < \epsilon < 1$.
- So by case 1 of the Master Theorem, we have that $T(n) = \Theta(n^{\log_2 4}) = \Theta(n^2)$.

Another example

• Consider the following recurrence relation:

$$T(n) = \begin{cases} 3T(\frac{n}{2}) + \Theta(n) & \text{if } n > 1\\ \Theta(1) & \text{if } n \leq 1 \end{cases}$$

• Apply the Master Theorem to show that the solution to this recurrence relation is $\mathcal{O}(n^{\log_2 3})$.

Solution

- $f(n) = \Theta(n) = \mathcal{O}(n^{\log_2 3 \epsilon})$ for any $0 < \epsilon < \log_2 3 1$
- Case 2 of master theorem \Rightarrow $T(n) = \Theta(n^{\log_2 3}) \Rightarrow T(n) = \mathcal{O}(n^{\log_2 3})$.
